

Internal / Inside hot water systems

Hot water heaters located inside a building require a safe tray to catch any water should the tank or pipework leak. Some properties will already have this and some may not. It is a regulation that all homes have this and if there is no drain that can be discharged externally and Mildred valve is required.

A Mildred valve is a safety valve that automatically isolates the water supply to the hot water system when the safe tray has water present, this prevents the building from flooding

This is a regulation and ALL internal hot water systems must have a tray

The only inside hot water systems that may get away with this is when they are in a garage or laundry where there is a drain or floor falls to a doorway
